A Modern Approach](#)

# Constraint Satisfaction Problems

## Special Type of search problem:

- state is defined by variables  $X_i$  with  $d$  values from domain  $D_i$
- goal test is a set of constraints specifying allowable combinations of values for subsets of variables

- Examples:
  - Sudoku

5	3		7

# Real-World CSPs

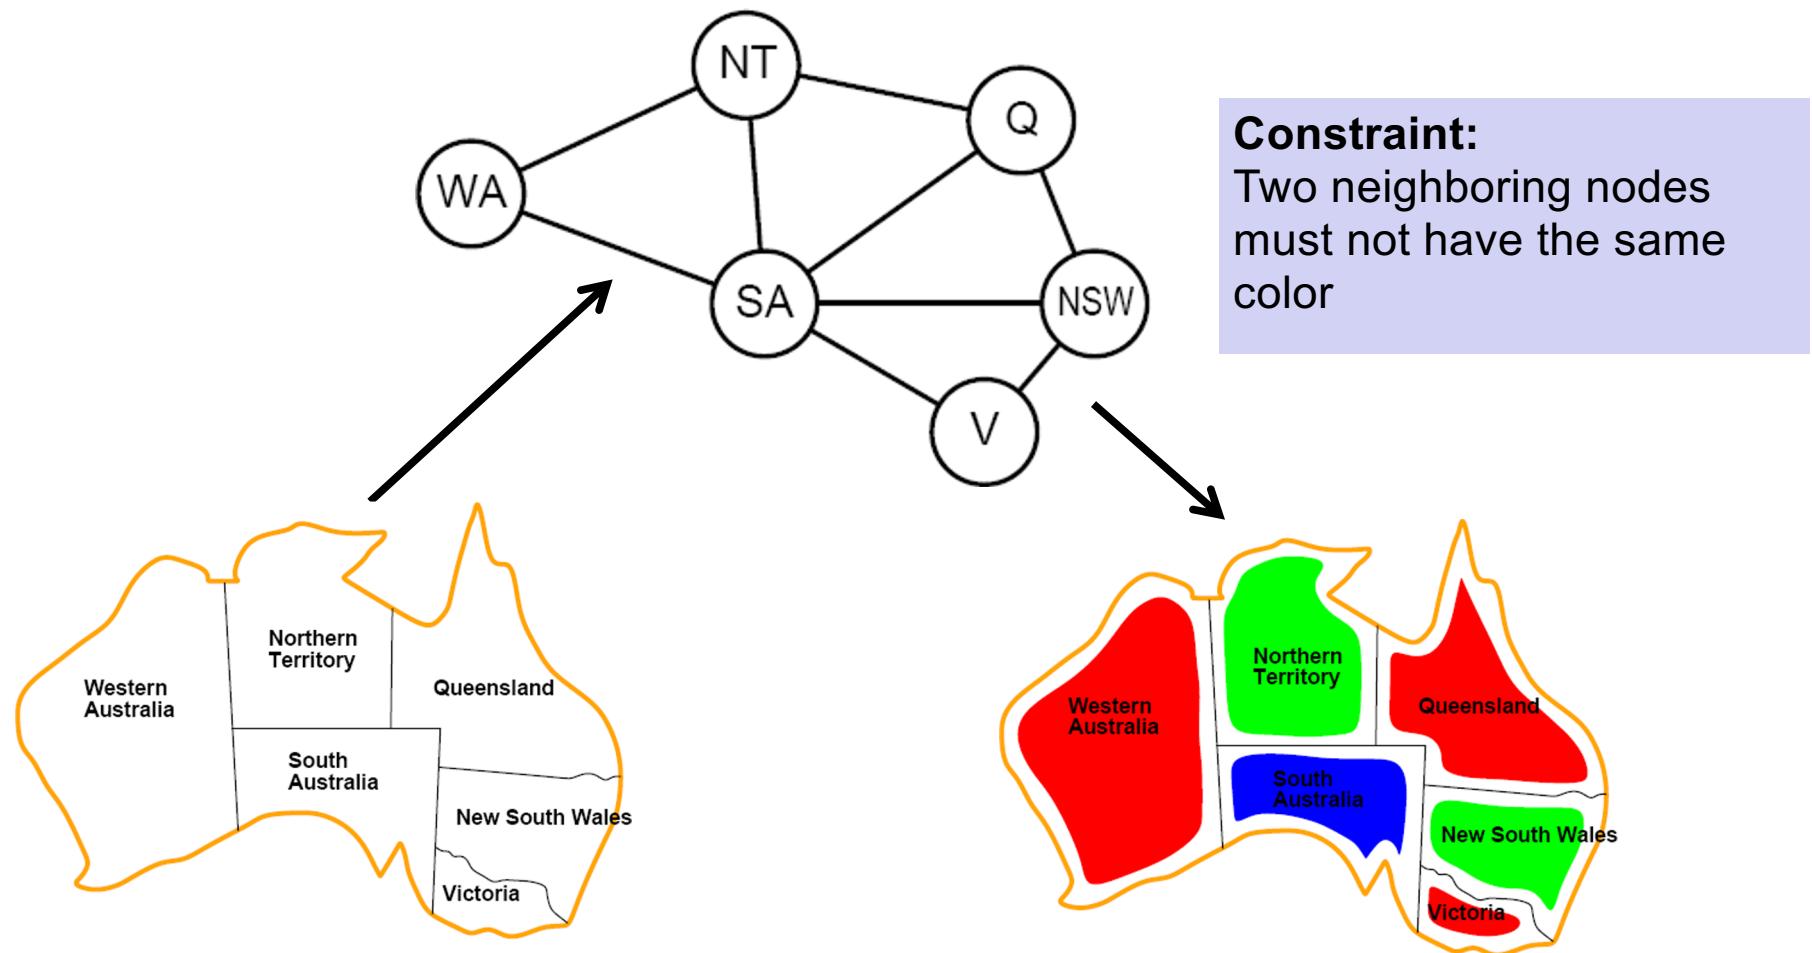

- Assignment problems
  - e.g., who teaches what class
- Timetabling problems
  - e.g., which class is offered when and where?
- Hardware configuration
- Spreadsheets
- Scheduling
  - Job scheduling
    - Constraints are, e.g., start and end times for each job
  - Transportation scheduling
  - Factory scheduling
- Floorplanning

**Note many real-world problems involve real-valued variables**

- Linear constraints solvable in polynomial time using linear programming
- Problems with nonlinear constraints undecidable

# Constraint Graph

1. **nodes** are variables
2. **edges** indicate constraints between them

# The Four Color Map Theorem

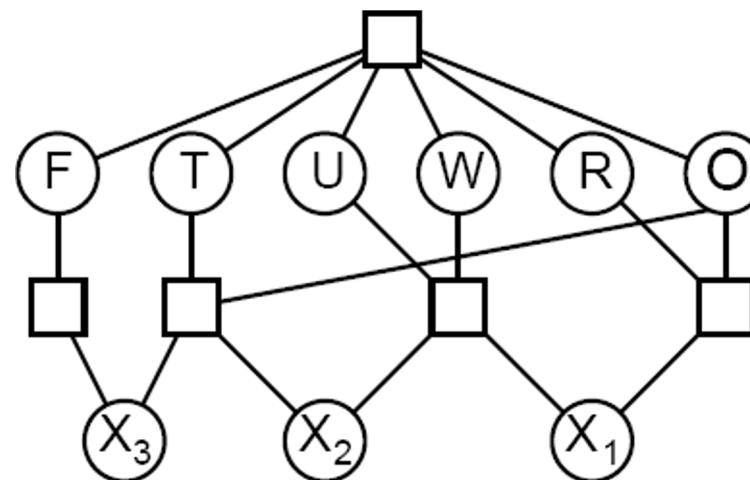

<https://www.youtube.com/watch?v=NgbK43jB4rQ&t=513s>

# Constraint Graph

- 1.** **nodes** are variables
- 2.** **edges** indicate constraints between them

$$\begin{array}{r} \text{T} \quad \text{W} \quad \text{O} \\ + \quad \text{T} \quad \text{W} \quad \text{O} \\ \hline \text{F} \quad \text{O} \quad \text{U} \quad \text{R} \end{array}$$

Connected nodes are involved in (in-)equations:

$$2 \cdot O = 10 \cdot X_1 + R$$

$$2 \cdot W + X_1 = 10 \cdot X_2 + U$$

$$2 \cdot T + X_2 = 10 \cdot X_3 + O$$

$$F = X_3$$

$$F \neq T \neq U \neq W \neq R \neq O$$

$$\begin{array}{r} 7 \quad 3 \quad 4 \\ + \quad 7 \quad 3 \quad 4 \\ \hline 1 \quad 4 \quad 6 \quad 8 \end{array}$$

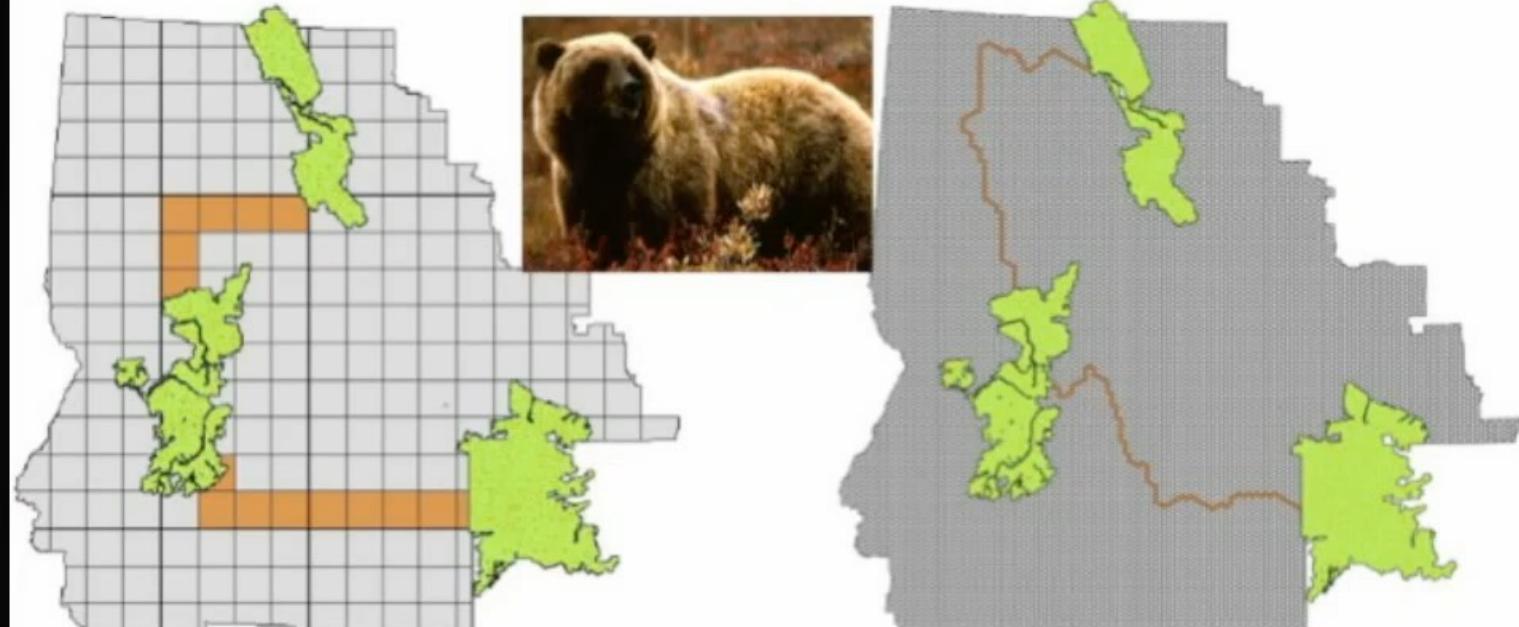

# Types of Constraints

- **Unary** constraints involve a single variable,
  - e.g., *South Australia*  $\neq$  *green*
- **Binary** constraints involve pairs of variables,
  - e.g., *South Australia*  $\neq$  *Western Australia*
- **Higher-order** constraints involve 3 or more variables
  - e.g.,  $2 \cdot W + X_1 = 10 \cdot X_2 + U$
- **Preferences** (soft constraints)
  - e.g., *red is better than green*
  - are not binding, but task is to respect as many as possible  
→ constrained optimization problems

# Wild-Life Corridor Design

<https://www.youtube.com/watch?v=vPluRAznFPw&t=211s>

Many problems are a combination of hard and soft constraints  
(aka optimization under constraints)

**Corridor design:** connect existing habitat reserves (e.g., shown in green); each parcel of land has a **cost** (e.g., purchase price) and a **utility** (e.g., habitability).  
**maximize the total (additive) utility of the corridor (soft constraint, optimization), without exceeding a fixed (total cost) budget (hard constraint, constraint satisfaction)**

Incorporating Economic and Ecological Information into the Optimal Design of Wildlife Corridors,

Douglas H. Fisher

# How do we solve CSP?

**Two principal approaches:**

## 1. Search:

- successively assign values to variable
- check all constraints
- if a constraint is violated → backtrack
- until all variables have assigned values

## 2. Constraint Propagation:

- maintain a set of possible values  $D_i$  for each variable  $X_i$
- try to reduce the size of  $D_i$  by identifying values that violate some constraints

# Solving CSPs with Search

- **Constraint problems define a simple search space:**
  - The start node is an empty assignment of values to variables
  - Its successors are all possible ways of assigning one value to a variable (depth 1)
  - Their successors are those with 2 variables assigned (depth 2)
  - ....
  - Until at the end all variables have been assigned a value (depth n)
  - **Goal test:** Does a node at depth n satisfy all constraints?
- **Observation:**
  - All solution nodes will appear at depth  $n \rightarrow$  depth-first search is feasible without losing completeness

# Naive Search

[https://www.youtube.com/watch?v=Hv\\_JIWId9iQ](https://www.youtube.com/watch?v=Hv_JIWId9iQ)

The screenshot shows a web browser window with the URL `file:///C:/Users/pabbeel/Desktop/SP14%20cs188%20Lecture%204%20CSPs%20I/backtracking-javascript-demo/forward_checking.html`. The main content area displays a graph of 9 nodes arranged in a 3x3 grid. Edges connect nodes between adjacent rows and columns. Below the graph are six buttons: Reset, Prev, Pause, Next, Play, and Faster.

On the right side, there are several configuration options:

- Graph:** A dropdown menu set to "Simple".
- Algorithm:** A dropdown menu set to "Naive Search".
- Ordering:** A section with three radio buttons:
  - None (selected)
  - MRV
  - MRV with LCV
- Filtering:** A section with three radio buttons:
  - None (selected)
  - Forward Checking
  - Arc Consistency
- Speed:** A section with two input fields:
  - Speedup: A slider set to 1.
  - Frame Delay: An input field set to 700.

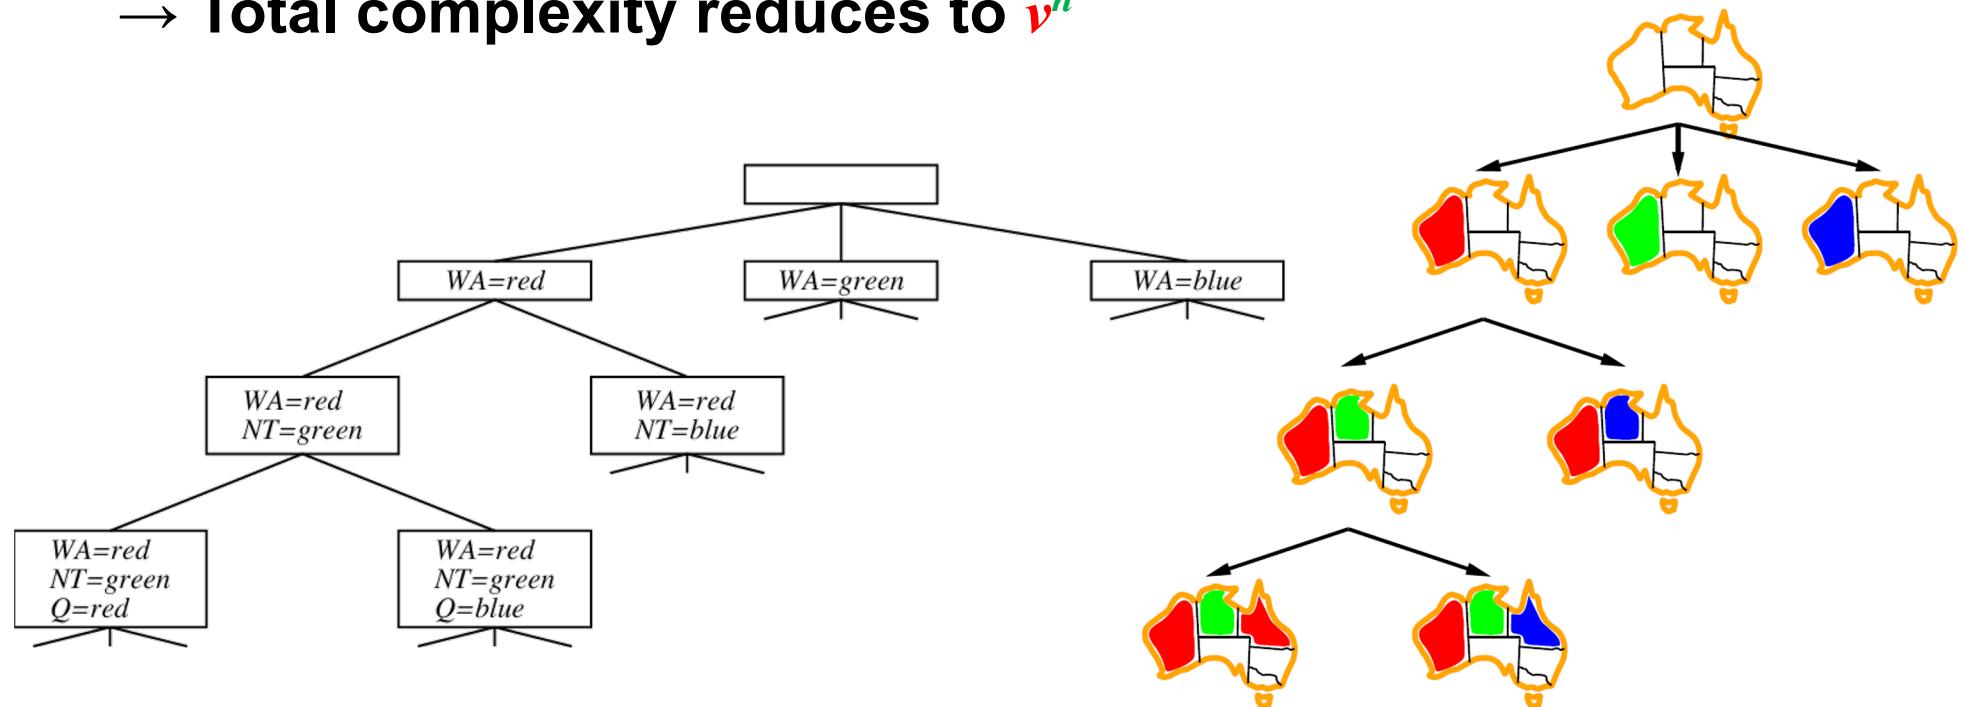

# Complexity of Naive Search

- Assumptions
  - we have  $n$  variables
    - all solutions are at depth  $n$  in the search tree
  - all variables have  $v$  possible values
- Then
  - at level 1 we have  $n \cdot v$  possible assignments
    - (we can choose one of  $n$  variables and one of  $v$  values for it)
  - at level 2, we have  $(n-1) \cdot v$  possible assignments for each previously assigned variable
    - (we can choose one of the remaining  $n-1$  variables and one of the  $v$  values for it)
  - In general: branching factor at depth  $l$ :  $(n-l+1) \cdot v$
- Hence
  - The search tree has  $n!v^n$  leaves

# We can do better!

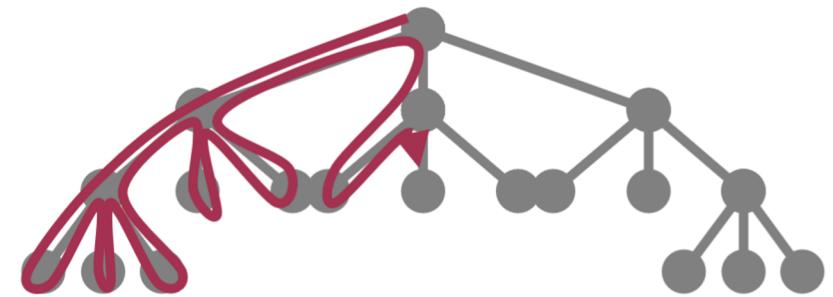

## Commutative Variable Assignments

- Variable assignments are commutative
  - $[WA = red \text{ then } NT = green]$  is the same as  $[NT = green \text{ then } WA = red]$
- Thus, at each node, we only need to make assignments for one of the variables  
→ **Total complexity reduces to  $v^n$**

# Backtracking Search

- Depth-first search with single variable assignments per level is also called **backtracking search**
- Backtracking is the basic uninformed search algorithm for CSPs
  - add one constraint at a time without conflict
  - succeed if a legal assignment is found
  - Can solve n-queens problems for up to  $n \approx 25$
- Complexity:
  - Worst case is still exponential
  - heuristics for selecting variables ( $\rightarrow$ SELECTUNASSIGNEDVARIABLE) and for ordering values ( $\rightarrow$ ORDERDOMAINVALUES) can improve practical performance

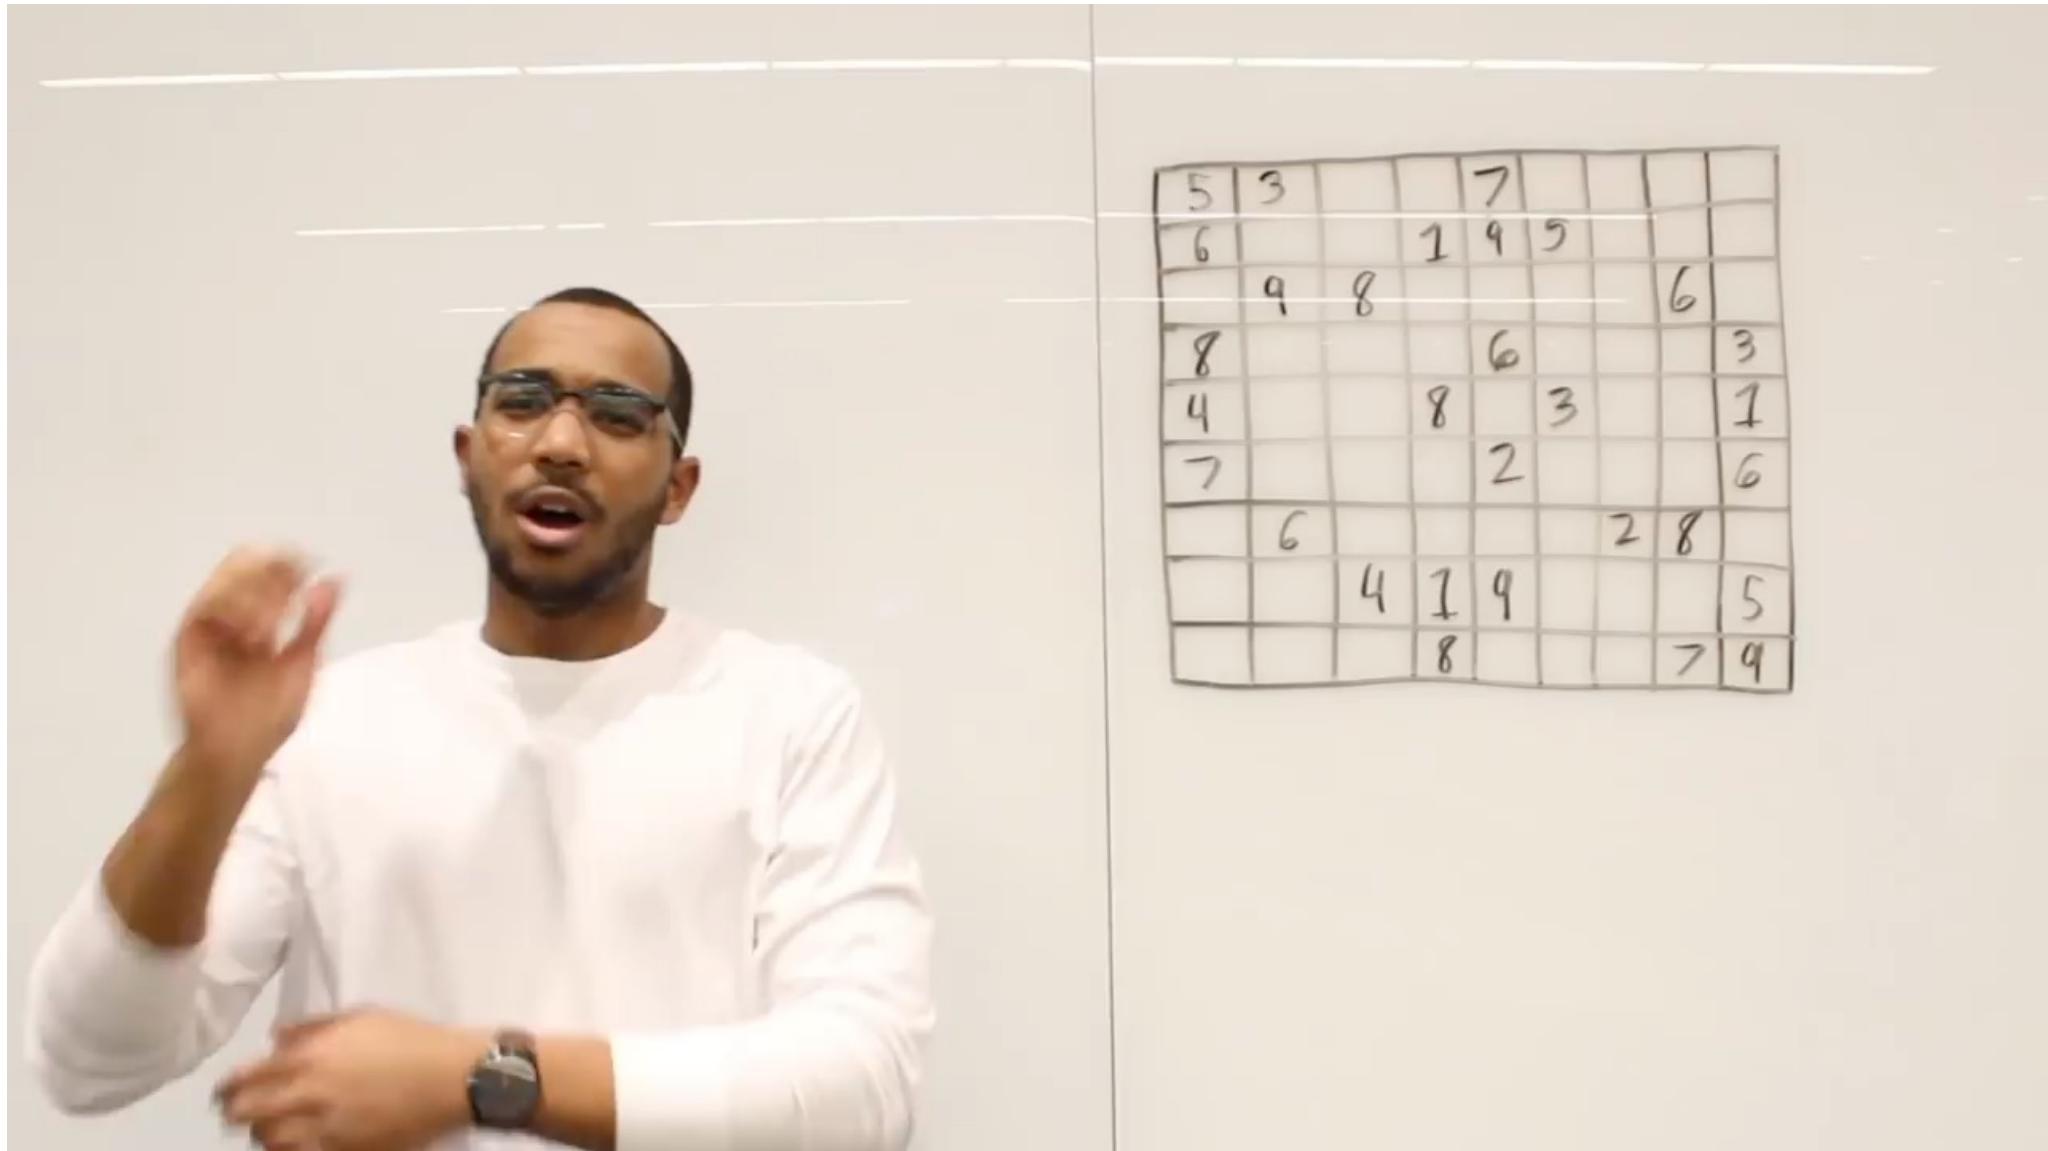

Graph taken from J. Hertzberg, Uni Osnabrück

# Backtracking Search

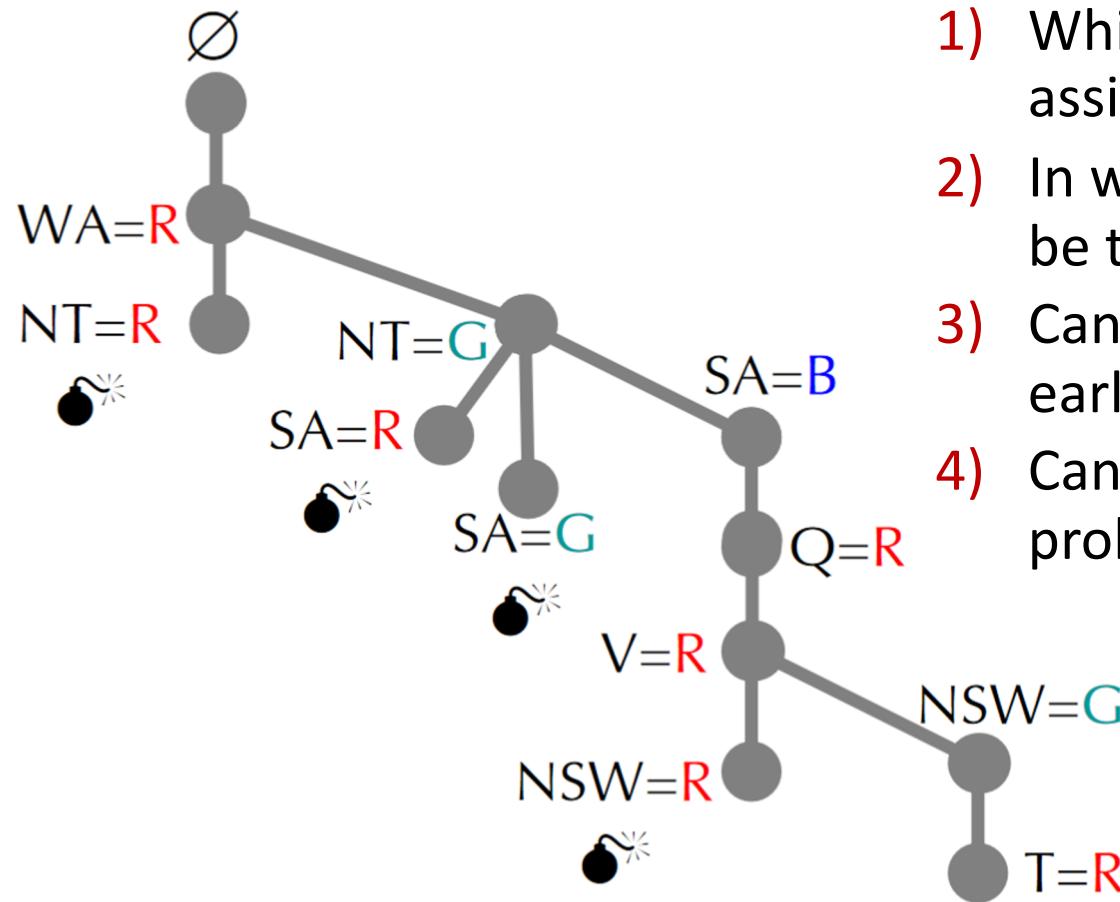

```
function BACKTRACKING-SEARCH(csp) returns solution/failure
    return RECURSIVE-BACKTRACKING({ }, csp)
function RECURSIVE-BACKTRACKING(assignment, csp) returns soln/failure
    if assignment is complete then return assignment
    var  $\leftarrow$  SELECT-UNASSIGNED-VARIABLE(VARIABLES[csp], assignment, csp)
    for each value in ORDER-DOMAIN-VALUES(var, assignment, csp) do
        if value is consistent with assignment given CONSTRAINTS[csp] then
            add {var = value} to assignment
            result  $\leftarrow$  RECURSIVE-BACKTRACKING(assignment, csp)
            if result  $\neq$  failure then return result
            remove {var = value} from assignment
    return failure
```

# Backtracking Search

<https://www.youtube.com/watch?v=Zq4upTEaQyM>

# Backtracking Search

General-purpose methods can give huge gains in speed:

- 1) Which variable should be assigned next?
- 2) In what order should its values be tried?
- 3) Can we detect inevitable failure early?
- 4) Can we take advantage of problem structure?

# Backtracking Search

[https://www.youtube.com/watch?v=Hv\\_JIWId9iQ](https://www.youtube.com/watch?v=Hv_JIWId9iQ)

## Backtracking Search

```
function BACKTRACKING-SEARCH(csp) returns solution/failure
    return RECURSIVE-BACKTRACKING({ }, csp)
function RECURSIVE-BACKTRACKING(assignment, csp) returns soln/failure
    ↗ if assignment is complete then return assignment
    ↗ var ← SELECT-UNASSIGNED-VARIABLE(VARIABLES[csp], assignment, csp)
    ↗ for each value in ORDER-DOMAIN-VALUES(var, assignment, csp) do
        ↗ if value is consistent with assignment given CONSTRAINTS[csp] then
            add {var = value} to assignment
            result ← RECURSIVE-BACKTRACKING(assignment, csp)
            if result ≠ failure then return result
            remove {var = value} from assignment
    ↗ return failure
```

- Backtracking = DFS + variable-ordering + fail-on-violation
- What are the choice points? ↗

[demo: backtracking]

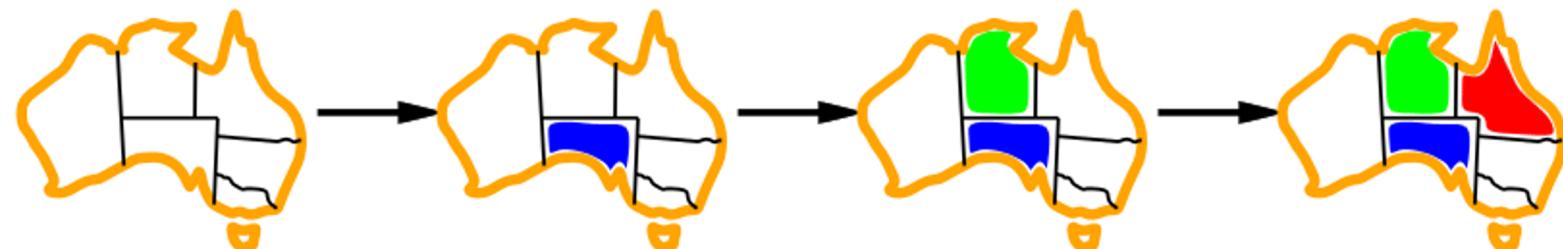

# How do we select heuristics? General Heuristics for CSP

- Domain-Specific Heuristics
  - Depend on the particular characteristics of the problem
  - Obviously, a heuristic for the 8-puzzle can not be used for the 8-queens problem
- General-purpose heuristics
  - For CSP, good general-purpose heuristics are known:
  - **Minimum Remaining Values Heuristic**
    - choose the variable with the fewest consistent values

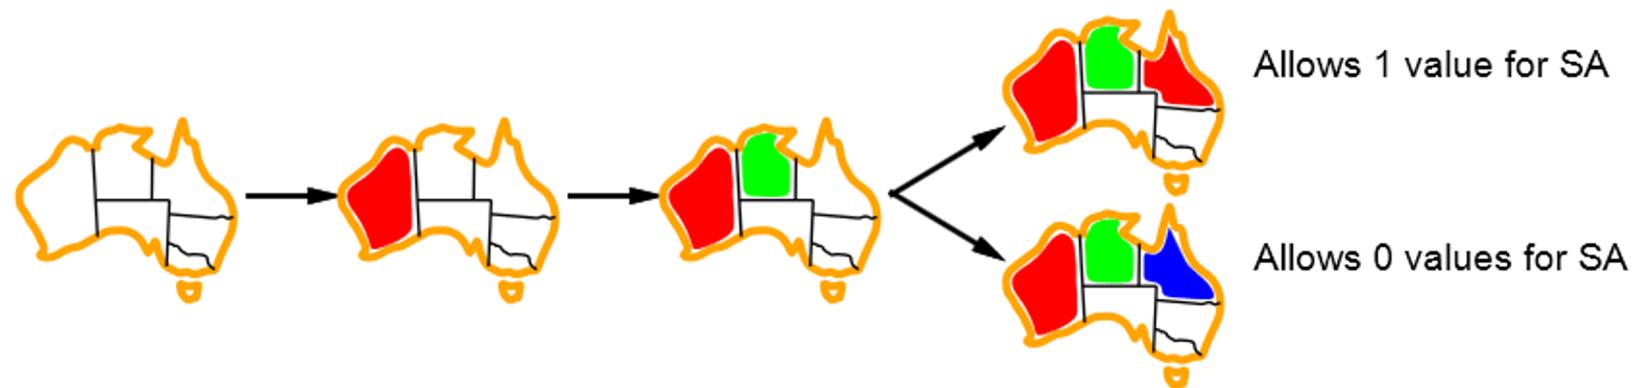

# How do we select heuristics? General Heuristics for CSP

- Domain-Specific Heuristics
  - Depend on the particular characteristics of the problem
  - Obviously, a heuristic for the 8-puzzle can not be used for the 8-queens problem
- General-purpose heuristics
  - For CSP, good general-purpose heuristics are known:
  - **Minimum Remaining Values Heuristic**
    - choose the variable with the fewest consistent values
  - **Degree Heuristic**
    - choose the variable with the most constraints on remaining variables

# How do we select heuristics? General Heuristics for CSP

- Domain-Specific Heuristics
  - Depend on the particular characteristics of the problem
  - Obviously, a heuristic for the 8-puzzle can not be used for the 8-queens problem
- General-purpose heuristics

- Least Constraining Value Heuristic
  - Given a variable, choose the value that rules out the fewest values in the remaining variables

# How do we select heuristics? General Heuristics for CSP

- Domain-Specific Heuristics
  - Depend on the particular characteristics of the problem
  - Obviously, a heuristic for the 8-puzzle can not be used for the 8-queens problem
- General-purpose heuristics
  - For CSP, good general-purpose heuristics are known:
  - Minimum Remaining Values Heuristic
    - choose the variable with the fewest consistent values
  - Degree Heuristic
    - choose the variable that imposes the most constraints on the remaining values
  - Least Constraining Value Heuristic
    - Given a variable, choose the value that rules out the fewest values in the remaining variables
  - used in this order, these three can greatly speed up search
    - e.g., n-queens from 25 queens to 1000 queens

# Constraint Propagation - Sudoku

- Problem
  - CSP with 81 variables
- Constraints
  - some values are assigned in the start (unary constraints)
  - 27 constraints on 9 values that must all be different  
(9 rows, 9 columns, 9 squares)
- Constraint Propagation
  - People often write a list of possible values into empty fields
  - try to successively eliminate values
- Status
  - Automated constraint solvers can solve the hardest puzzles in no time

Figure 6

# Node Consistency

## Node Consistency

- the possible values of a variable must conform to all unary constraints
- can be trivially enforced
- Example:
  - Sudoku: Some nodes are already filled out, i.e., constrained to a single value

## More General Idea: Local Consistency

- make each node in the constraint graph consistent with its neighbors
- by (iteratively) enforcing the constraints corresponding to the edges

# Forward Checking

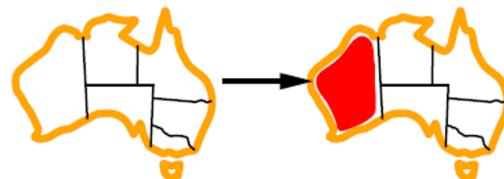

- Idea:
  - keep track of remaining legal values for unassigned variables
  - terminate search when any variable has no more legal values

# Forward Checking

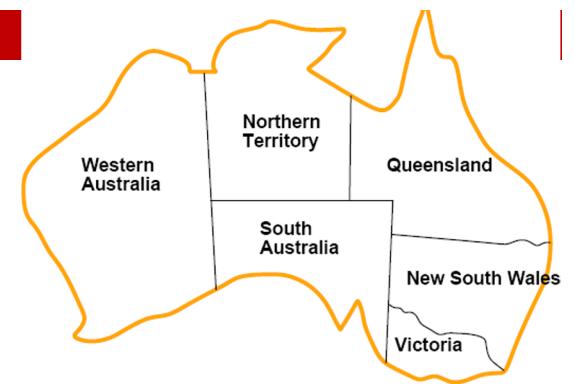

- Idea:
    - keep track of remaining legal values for unassigned variables
    - terminate search when any variable has no more legal values

State/Territory	Red (%)	Green (%)	Blue (%)
WA	40	30	30
NT	40	40	20
Q	40	30	30
NSW	40	40	20
V	40	30	30
SA	40	30	30
T	40	30	30

# Forward Checking

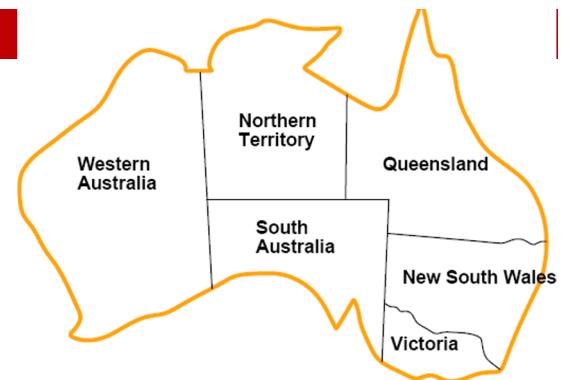

- Idea:
  - keep track of remaining legal values for unassigned variables
  - terminate search when any variable has no more legal values

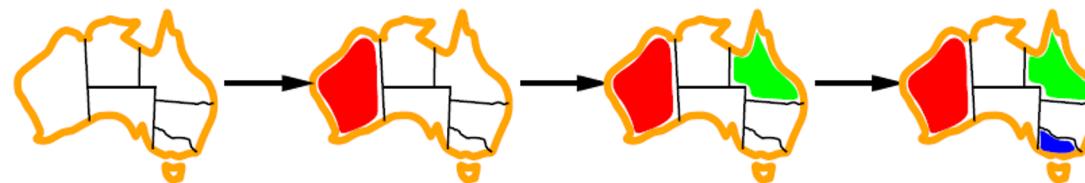

WA	NT	Q	NSW	V	SA	T
Red	Green	Blue	Red	Green	Blue	Red
Red		Green	Blue	Red	Green	Blue
Red		Blue	Green	Red	Blue	Red

# Forward Checking

- Idea:
    - keep track of remaining legal values for unassigned variables
    - terminate search when any variable has no more legal values

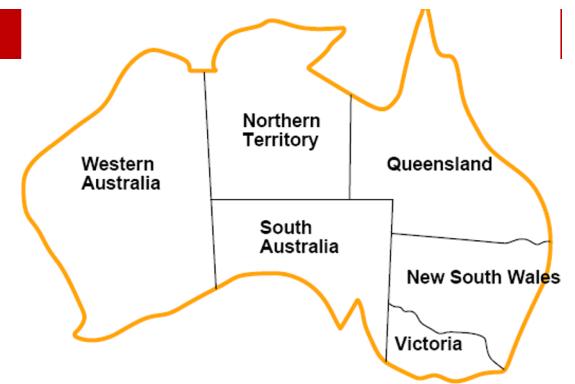

The figure consists of seven horizontal rows, each representing a state or territory of Australia: Western Australia (WA), Northern Territory (NT), Queensland (Q), New South Wales (NSW), Victoria (V), South Australia (SA), and Tasmania (T). Each row contains colored squares representing different categories. The colors used are red, green, and blue.

- Row 1:** WA has red, green, blue; NT, Q, NSW, V, SA have red, green, blue.
- Row 2:** NT has red; Q, NSW, V, SA have red, green, blue; T has red, green, blue.
- Row 3:** WA has red; NT has blue; Q, NSW, V, SA have red, green, blue; T has red, green, blue.
- Row 4:** WA has red; NT has blue; Q, NSW, V, SA have red; T has red, green, blue.

no further assignment possible

# Constraint Propagation

- Problem:
  - forward checking propagates information from assigned to unassigned variables
  - **but doesn't look ahead to provide early detection for all failures**

**One step earlier,  
we could have seen  
already the conflict!**

WA	NT	Q	NSW	V	SA	T
Red	Green	Blue	Red	Green	Blue	Red
Red	Green	Blue	Red	Green	Blue	Red
Red	Blue	Green	Red	Blue	Green	Red

only one of them can be blue!

# Arc Consistency

- **Every domain must be consistent with the neighbors:**

A variable  $X_i$  is **arc-consistent** with a variable  $X_j$  if

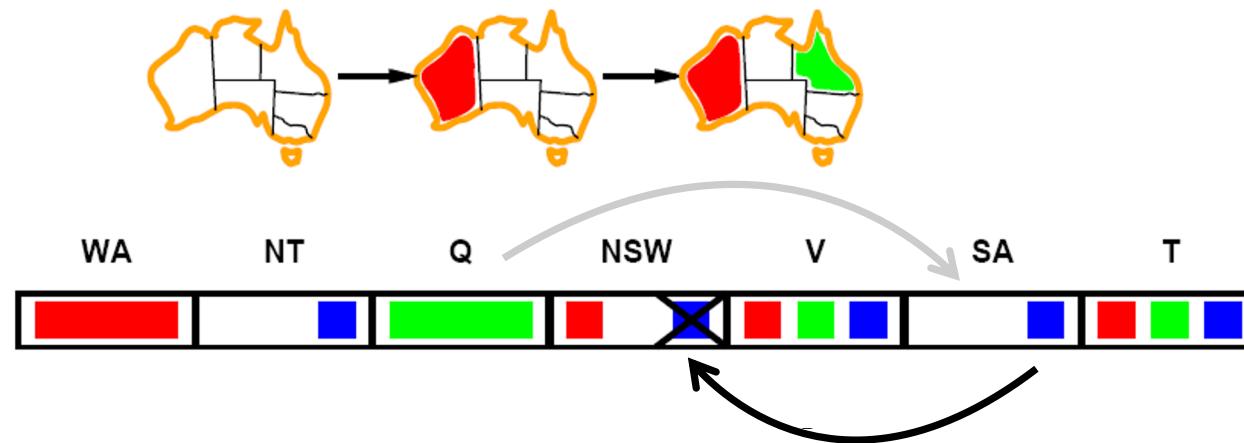

- for every value in its domain  $D_i$
- there is some value in  $D_j$
- that satisfies the constraint on the arc  $(X_i, X_j)$

- can be generalized to n-ary constraints
  - each tuple involving the variable  $X_i$  has to be consistent

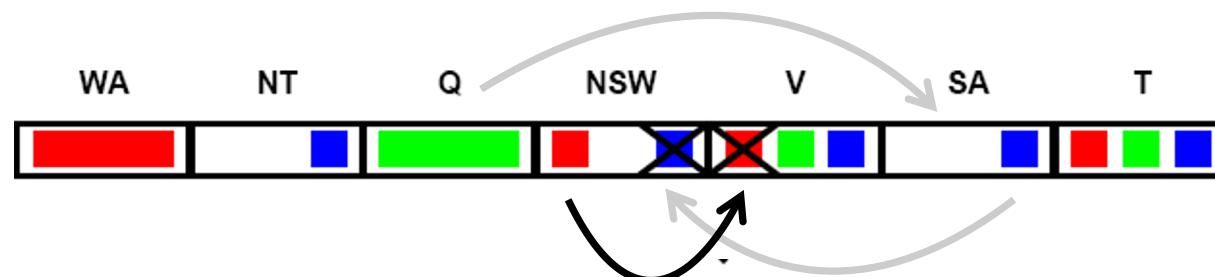

**We check edges!**

# Maintaining Arc Consistency (MAC)

- After each new assignment of a value to a variable, possible values of the neighbors have to be updated:

- If one variable (NSW) loses a value (blue), we need to **recheck** its **neighbors** as well because they **might have lost a possible value**

# Arc Consistency Algorithm

**function** AC-3(*csp*) **returns** the CSP, possibly with reduced domains

**inputs:** *csp*, a binary CSP with variables  $\{X_1, X_2, \dots, X_n\}$

**local variables:** *queue*, a queue of arcs, initially all the arcs in *csp*

**while** *queue* is not empty **do**

$(X_i, X_j) \leftarrow \text{REMOVE-FIRST}(\text{queue})$

**if** REMOVE-INCONSISTENT-VALUES( $X_i, X_j$ ) **then**

**for each**  $X_k$  **in** NEIGHBORS[ $X_i$ ] **do**

        add  $(X_k, X_i)$  to *queue*

If  $X$  loses a value,  
neighbors of  $X$  need  
to be rechecked.

**function** REMOVE-INCONSISTENT-VALUES( $X_i, X_j$ ) **returns** true iff succeeds

*removed*  $\leftarrow$  false

**for each** *x* **in** DOMAIN[ $X_i$ ] **do**

**if** no value *y* in DOMAIN[ $X_j$ ] allows  $(x, y)$  to satisfy the constraint  $X_i \leftrightarrow X_j$

**then** delete *x* from DOMAIN[ $X_i$ ]; *removed*  $\leftarrow$  true

**return** *removed*

- Run-time:  $O(n^2d^3)$  (can be reduced to  $O(n^2d^2)$ )
- more efficient than forward checking

# Path Consistency

- Arc Consistency is often sufficient to
    - solve the problem (all variable domains are reduced to size 1)
    - show that the problem cannot be solved (some domains empty)
  - but may not be enough
    - there is always a consistent value in the neighboring region
- **Path consistency**
  - tightens the binary constraints by considering triples of values

A pair of variables  $(X_i, X_j)$  is **path-consistent** with  $X_m$  if

- for every assignment that satisfies the constraint on the arc  $(X_i, X_j)$
- there is an assignment that satisfies the constraints on the arcs  $(X_i, X_m)$  and  $(X_j, X_m)$

**We check triangles!**

- Algorithm AC-3 can be adapted to this case (known as PC-2)

# k-Consistency

- The concept can be generalized so that a set of  $k$  values need to be consistent
  - 1-consistency = node consistency
  - 2-consistency = arc consistency
  - 3-consistency = path consistency
  - ....
- May lead to faster solution but checking for  $k$ -Consistency is exponential in  $k$  in the worst case
- therefore arc consistency is most frequently used in practice

# Sudoku

- simple puzzles can be solved with AC-3
  - the puzzle has 9 constraints on the rows, 9 on the columns and 9 on the square (27 in total)
    - each such constraint requires that 9 values are all different
  - these 9-valued AllDiff constraints can be converted into pairwise binary constraints
    - $9 \times 8 / 2 = 36$  pairwise constraints
  - therefore  $27 \times 36 = 972$  arc constraints
- somewhat more with PC-2
  - there are 255,960 path constraints
- however, not all problems can be solved with constraint propagation alone
  - **to solve all puzzles we need a bit of search**

# Integrating Constraint Propagation and Backtracking Search

- Performance of Backtracking can be further sped up by integrating constraint propagation into the search
- Key idea:
  - each time a variable is assigned, a constraint propagation algorithm is run in order to reduce the number of choice points in the search
- Possible algorithms
  - Forward Checking
  - AC-3, but initial queue of constraints only contains constraints with the variable that has been changed

# Illustration CP + Search

At the bottom left, there are navigation buttons: Reset, Prev, Pause, Next, Play, and Faster.

# Local Search for CSP

- **Modifications for CSPs:**
  - work with complete states
  - allow states with unsatisfied constraints
  - operators reassign variable values

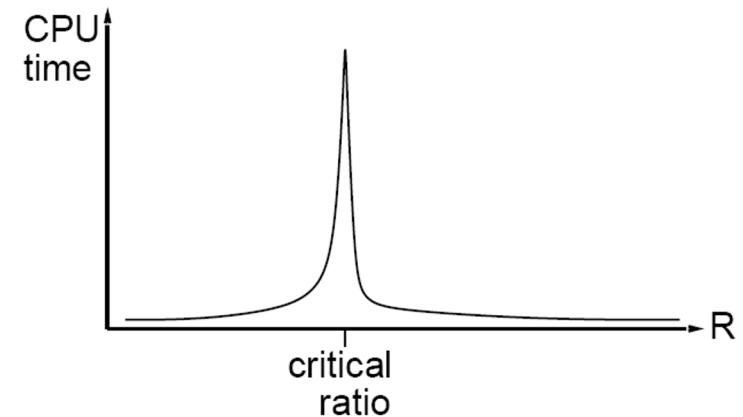

18	12	14	13	13	12	14	14
14	16	13	15	12	14	12	16
14	12	18	13	15	12	14	14
15	14	14	14	13	16	13	16
14	14	17	15	14	16	16	16
17	14	16	18	15	14	15	15
18	14	14	15	15	14	14	16
14	14	13	17	12	14	12	18

- **Min-conflicts Heuristic:**
  - randomly select a conflicted variable
  - choose the value that violates the fewest constraints
  - hill-climbing with  $h(n) = \#$  of violated constraints

Min-conflicts is the heuristic that we studied for the 8-queens problems.

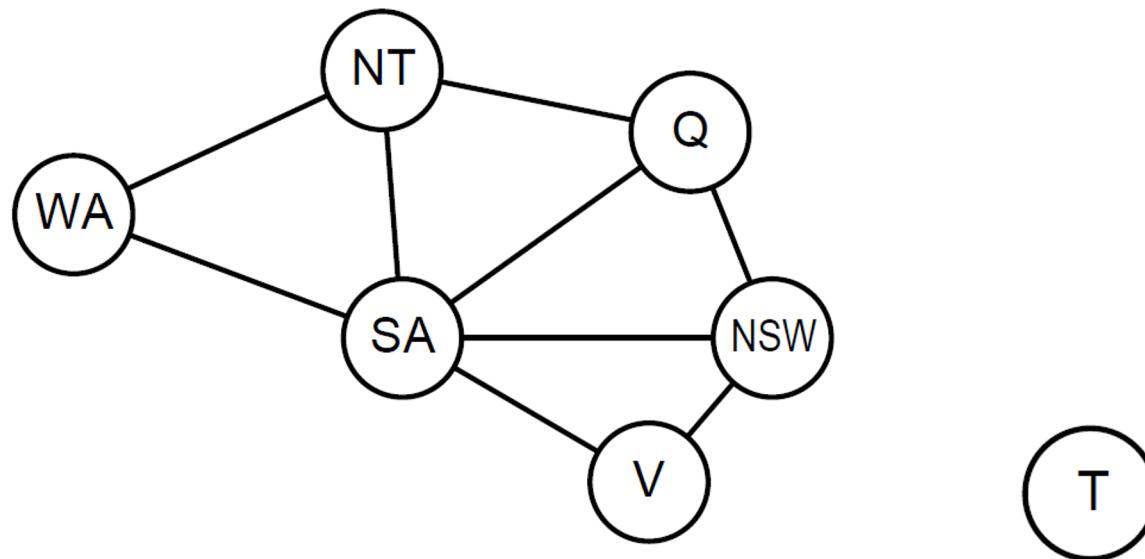

- **Performance:**
  - can solve randomly generated CSPs with a high probability
  - except in a narrow range of

$$R = \frac{\text{number of constraints}}{\text{number of variables}}$$

# Problem Structure

- Decomposing the problem into independent subproblems

- The problem of coloring Tasmania is **independent** of the problem of coloring the mainland of Australia

# The Power of Problem Decomposition

- Search space for a constraint satisfaction with  $n$  variables, each of which can have  $d$  values =  $O(d^n)$
  - Decomposing the problem into subproblems with  $c$  variables each:
    - Each problem has complexity =  $O(d^c)$
    - There are  $n/c$  such problems
- Total complexity =  $O(n/c \cdot d^c)$
- Thus the total complexity can be reduced from exponential in  $n$  to linear in  $n$  (assuming that  $c$  is a constant parameter) !
  - Example:

E.g.,  $n = 80$ ,  $d = 2$ ,  $c = 20$

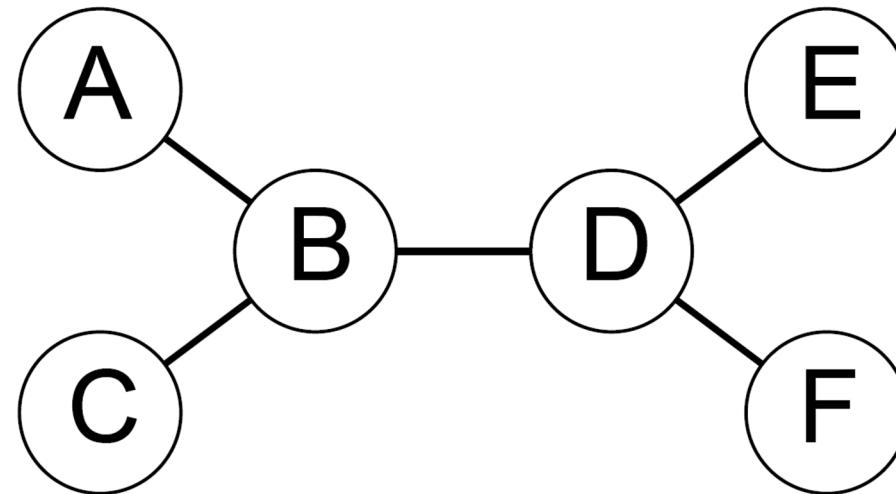

$2^{80} = 4$  billion years at 10 million nodes/sec

$4 \cdot 2^{20} = 0.4$  seconds at 10 million nodes/sec

Unconditional  
Independence  
is powerful  
but rare!

# Tree-Structured CSP

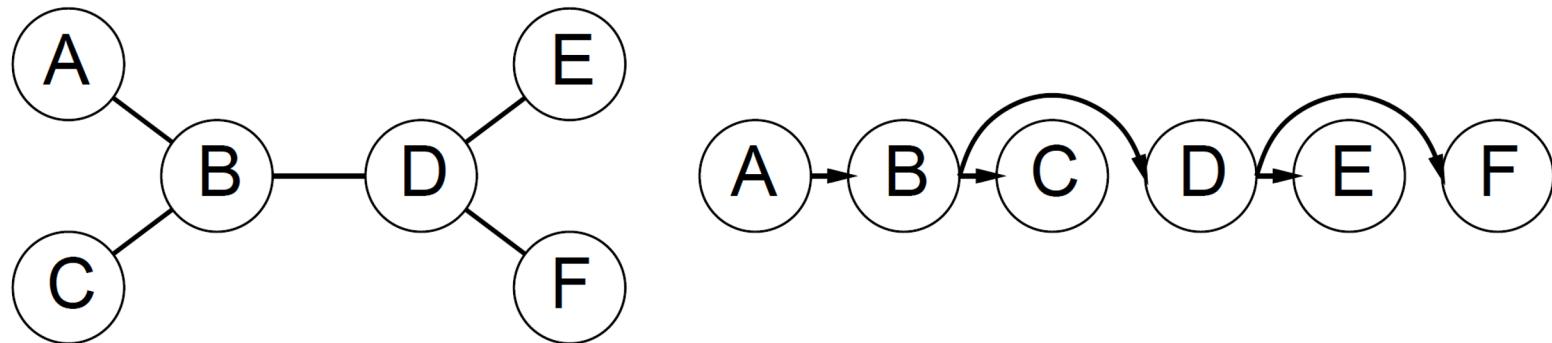

- A CSP is tree-structured if in the constraint graph any two variables are connected by a single path

**Theorem:** Any tree-structured CSP can be solved in linear time in the number of variables (more precisely:  $O(n \cdot d^2)$ )

# Linear Algorithm for Tree-Structured CSPs

- 1) Choose a variable as a root, order nodes so that a parent always comes before its children (each child can have only one parent)

- 2) For  $j = n$  downto 2
  - Make the arc  $(X_i, X_j)$  arc-consistent, calling REMOVE-INCONSISTENT-VALUE( $X_i, X_j$ )
- 3) For  $i = 1$  to  $n$ 
  - Assign to  $X_i$  any value that is consistent with its parent.

# Nearly Tree-structured Problems

- Tree-structured problems are also rare.
- Most maps are clearly not tree-structured...
  - Exception: Sulawesi

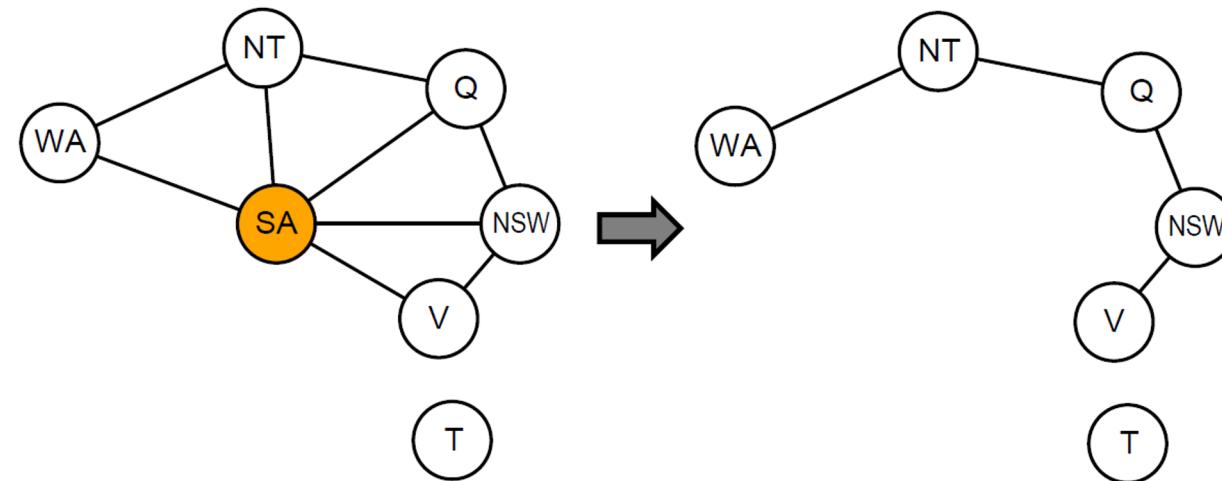

- Two approaches for making problems tree-structured:
  - Removing nodes so that the remaining nodes form a tree (cutset conditioning)
  - Collapsing nodes together (decompose the graph into a set of independent tree-shaped subproblems)

# Cutset Conditioning

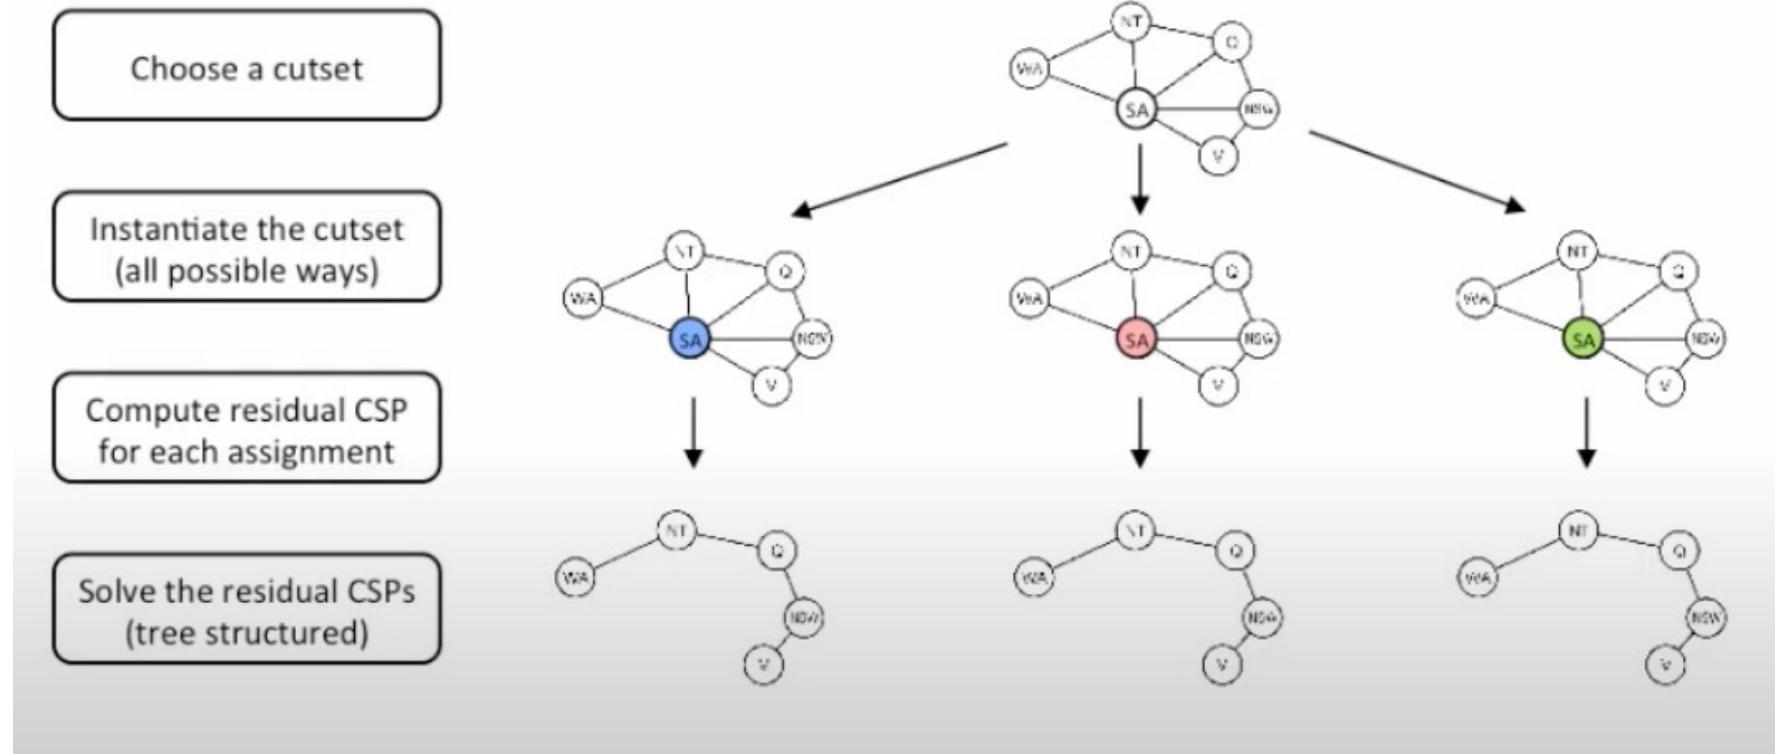

- 1) Choose a subset  $S$  of the variables such that the constraint graph becomes a tree after removal of  $S$  (= the *cycle cutset*)

Example:  $S = \{\text{SA}\}$

- 2) Choose a (consistent) assignment of variables for  $S$
- 3) Remove from the remaining variables all values that are inconsistent with the variables of  $S$
- 4) Solve the CSP problem for the remaining variables
- 5) If no solution → choose a different assignment for variables in 2)

# Cutset Conditioning

# Summary

- CSPs are a special kind of problem:
  - states defined by values of a fixed set of variables
  - goal test defined by constraints on variable values
- Backtracking = depth-first search with one variable assigned per node
- Variable ordering and value selection heuristics help significantly
- Forward checking prevents assignments that guarantee later failure
- Constraint propagation (e.g., arc consistency) does additional work
  - to constrain values and detect inconsistencies
- The CSP representation allows analysis of problem structure
- Tree-structured CSPs can be solved in linear time
